

The generator: a causal transformer that writes a peptide one residue at a time

4,767,255 parameters = embeddings 22,272 + six pre-norm blocks 4,738,560 + output head 5,911 + final norm 512. Inference only; the checkpoint is frozen.

What makes it autoregressive

A causal mask lets each place attend only to the places at or before it, so the score at place i never sees residue $i+1$. Sampling then runs left to right: draw a symbol from the softmax at the last place, append it, feed the longer sequence back in, and stop at $\langle \text{eos} \rangle$ or at length 50.
